Q: Complex Spring Beans I have an application that has a number of Spring beans, which create objects using constructor injection. These beans are referenced in other beans, for example: `public class MyMainBean { @Autowired private MyBean bean; }` and `public class MyBean { private OtherBean otherBean; }` What I need to do is to create a separate test environment, which would have some beans injected using the `@Primary` annotation. All of the dependencies are configured correctly in this test environment, but in order to access them I have to create a `BeanManager` (to get bean names) and use reflection, as I cannot use them in the `@Autowired` annotation. I am looking for a way to make this setup of beans available in all of my test environments, so that the code would look like: `public class MyMainBean { @Autowired private BeanManager beanManager; @Autowired private MyBean bean; }` I have tried to inject these beans using `@MockBean`, but that doesn't allow me to use constructor injection. Is there a way to configure beans in such a way that they can be injected using both `@Autowired` and `@MockBean`? A: I came up with a hack to get this to work: Create a new class `public class PrimaryBeans { @Resource(name="beanManager") private BeanManager beanManager; public BeanManager getBeanManager() { return beanManager; } }` In your Spring context file, replace 2d92ce491b
