Upgrading the memcached service Some applications cache data from a database or another service, and in those cases, it's desirable to have a way to restore these cached data when they are needed. One way to do this is to run a daemon that will periodically check the database and update the memcached service when data has changed. To do this, you need to update the configuration file `/etc/memcached.conf`. The following configuration line tells memcached to monitor `/var/lib/pgsql/data/memcached` and automatically reload all servers in that directory if it detects a change to any of them. In the example below, this file contains a list of database servers, so you'd change this to contain a list of any other servers that you want to monitor. `monitor-uri /var/lib/pgsql/data/memcached` If you want to completely replace memcached with a new version, it's not necessary to restart your system. The new version of the daemon can find the old version of the service and will handle everything else automatically. To do this, edit `/etc/init.d/memcached` and remove the `--service` line. This line tells the init script to automatically start the memcached daemon when the system is started. Microscopic and ultrastructural changes in the spermatozoa of a patient with Turner syndrome and oocyte donation. A case of oocyte donation was evaluated by light and electron microscopy in order to evaluate the ultrastructural effects of genetic abnormalities on sperm cells. The patient was a 31-year-old woman with Turner syndrome and underwent oocyte donation. She was found to have a low fertilization rate. We found a thickened sperm tail and also protoplasmic droplets on the head of the spermatozoa. The
